

DESCRIPTION

FLUOROPOLYMER, PROCESS FOR PRODUCING FLUOROPOLYMER,
ELECTROLYTE FILM, OBJECT HAVING IMMOBILIZED ACTIVE
5 SUBSTANCE, AND SOLID POLYMER ELECTROLYTE TYPE FUEL CELL

TECHNICAL FIELD

The present invention relates to a fluoropolymer, a
method of fluoropolymer production, an electrolyte membrane,
10 an immobilized active substance material, a membrane-
electrode assembly and a solid polymer electrolyte fuel
cell.

BACKGROUND ART

15 It is known that unstable terminal groups occurring
in a fluoropolymer cause not only foaming in the step of
melt molding but also deterioration of the moldings
manufactured from the fluoropolymer.

Typical unstable fluoropolymer terminal groups are
20 carboxyl groups among others, and a method of stabilizing
the same is known which comprises converting them into $-CF_3$
groups using a fluorinating agent (cf. e.g. Patent Document
1: Japanese Kokoku Publication S46-23245). However, this
method has certain problems; fluorine gas is to be used, an
25 expensive corrosion-resistant apparatus is required, and a
rise in expenditure results.

Another method of stabilizing carboxyl groups is
known which comprises causing a $-COOH$ -containing
fluoropolymer to undergo decarboxylation in the presence of
30 not more than 2% by mass of water for conversion to a more
stable $-CF_2H$ -containing fluoropolymer (cf. e.g. Patent
Document 2: Japanese Kokoku Publication S37-3127). This
document, however, gives no description of or suggestion
about the hygroscopicity of a fluoropolymer having such
35 specific functional groups as sulfonic acid groups.

DISCLOSURE OF INVENTION

PROBLEMS WHICH THE INVENTION IS TO SOLVE

In view of the above-mentioned state of the art, it
 5 is an object of the present invention to provide a
 fluoropolymer improved in stability and a simple method of
 obtaining such fluoropolymer.

MEANS FOR SOLVING THE PROBLEMS

10 The present invention relates to a fluoropolymer
 containing acid/acid salt groups and having $-CF_2H$ groups at
 polymer chain terminals,

wherein said acid/acid salt groups are sulfonic acid
 groups, $-SO_2NR^1R^2$, $-SO_3NR^3R^4R^5R^6$, $-SO_3M^1_{1/L}$, phosphoric acid
 15 groups, $-PO_3(NR^7R^8R^9R^{10})_2$ and/or $-PO_3M^2_{2/L}$, in the formula R^1
 represents H or $M^6_{1/L}$, R^2 represents H, $M^7_{1/L}$, an alkyl group
 or a sulfonyl-containing group, R^3 , R^4 , R^5 , R^6 , R^7 , R^8 , R^9
 and R^{10} are the same or different and each represents H or
 an alkyl group containing 1 to 4 carbon atoms, M^1 , M^2 , M^6
 20 and M^7 are the same or different and each represents a
 metal having a valence of L, said metal having a valence of
 L being a metal belonging to the group 1, 2, 4, 8, 11, 12
 or 13 of the long-form periodic table.

The present invention relates to a method of
 25 producing the fluoropolymer mentioned above, by subjecting
 a fluoropolymer precursor containing acid/acid salt groups
 and having $-CF_2COOX$ groups at polymer chain terminals, in
 the formula X represents H, $NR^{11}R^{12}R^{13}R^{14}$ or $M^4_{1/L}$; R^{11} , R^{12} , R^{13}
 and R^{14} are the same or different and each represents H or
 30 an alkyl group containing 1 to 4 carbon atoms and M^4
 represents a metal having a valence of L, said metal having
 a valence of L being as defined above, to heat treatment
 for the conversion of said $-CF_2COOX$ groups to $-CF_2H$ groups,
 X being as defined above,

35 wherein said fluoropolymer precursor is one obtained

by polymerizing a perhalovinyl ether derivative represented by the general formula (I):

wherein Y^1 represents F, Cl or a perfluoroalkyl group, n represents an integer of 0 to 3, the n atoms/groups of Y^1 are the same or different, Y^2 represents F or Cl, m represents an integer of 1 to 5, the m atoms of Y^2 are the same or different and Z represents F, Cl, Br, I, $-\text{OM}^5_{1/L}$ or $-\text{ONR}^{15}\text{R}^{16}\text{R}^{17}\text{R}^{18}$; M^5 represents a metal having a valence of L and the metal having a valence of L is as defined above, and R^{15} , R^{16} , R^{17} and R^{18} are the same or different and each represents H or an alkyl group containing 1 to 4 carbon atoms,

when the group $-\text{SO}_2\text{Z}$ in the general formula (I) is not said acid/acid salt group but is a group convertible to such acid/acid salt group, said fluoropolymer precursor is one subjected to a conversion treatment, after the above-mentioned polymerization, for the conversion of said group $-\text{SO}_2\text{Z}$ to the above-mentioned acid/acid salt group, and said heat treatment comprises heating said fluoropolymer precursor at 120 to 400°C.

The present invention relates to an electrolyte membrane comprising the fluoropolymer mentioned above.

The present invention relates to an immobilized active substance material comprising the fluoropolymer mentioned above and an active substance.

The present invention relates to a membrane-electrode assembly comprising the immobilized active substance material mentioned above.

The present invention relates to a solid polymer electrolyte fuel cell comprising the membrane-electrode assembly mentioned above.

The present invention relates to a solid polymer electrolyte fuel cell comprising the electrolyte membrane mentioned above.

In the following, the invention is described in detail.

The fluoropolymer of the invention contains acid/acid salt groups and has $-\text{CF}_2\text{H}$ groups at polymer chain terminals.

5 The above phrase "polymer chain terminal" means "polymer main chain terminal".

The fluoropolymer of the invention may be any one containing acid/acid salt groups and having $-\text{CF}_2\text{H}$ groups at main chain terminals, but not exclusion of one having $-\text{CF}_2\text{H}$ groups not only at main chain terminals but also at side chain terminals.

The above-mentioned fluoropolymer preferably has a content (mmol) of $-\text{CF}_2\text{H}$ groups, per kilogram of the polymer, of 0.3 to 22 mmol/kg, more preferably 0.5 to 18 mmol/kg.

15 When the fluoropolymer has a $-\text{CF}_2\text{H}$ content within the above range, a Fenton's reagent-based stability test, which is to be described later herein, generally gives a fluoride ion concentration of not higher than 12 ppm, preferably not higher than 10 ppm.

20 In the present specification, when polymer side chain terminals are referred to, the term "polymer side chain terminals" is used and, by merely saying "polymer chain terminals", it is meant that polymer main chain terminals are referred to.

25 The fluoropolymer of the invention is preferably a perfluoropolymer.

The acid/acid salt groups can be classified into acid groups and acid salt groups.

The acid groups each is a sulfonic acid group, -
30 $\text{SO}_2\text{NHR}^{19}$ or a phosphoric acid group.

The above symbol R^{19} represents H, an alkyl group or a sulfonyl-containing group.

The alkyl group is not particularly restricted but includes alkyl groups containing 1 to 4 carbon atoms, for
35 example methyl and ethyl. The alkyl group may be one in

which one or more H atoms are substituted by one or more F, Cl, Br and/or I atoms.

The sulfonyl-containing group is a sulfonyl group-containing fluoroalkyl group, for example a
 5 fluoroalkylsulfonyl group, which may optionally contain a terminal substituent(s). The fluoroalkylsulfonyl group is, for example, $-\text{SO}_2\text{R}_f^1\text{Z}^2$ (in which R_f^1 represents a fluoroalkylene group and Z^2 represents an organic group). The organic group is, for example, $-\text{SO}_2\text{F}$, and the
 10 fluoroalkylsulfonyl group may be such an indefinite number of repetitions as $-\text{SO}_2(\text{NR}^{19}\text{SO}_2\text{R}_f^1\text{SO}_2)_k\text{NR}^{19}\text{SO}_2-$ (in which k represents an integer of not smaller than 1 and R_f^1 represents a fluoroalkylene group) or, for example, $-\text{SO}_2(\text{NR}^{19}\text{SO}_2\text{R}_f^1\text{SO}_2)_k\text{NR}^{19}\text{SO}_2\text{F}$ (in which k is an integer of not
 15 smaller than 1 but not greater than 100 and R^{19} and R_f^1 are as defined above).

The above-mentioned acid salt groups are $-\text{SO}_3\text{NR}^3\text{R}^4\text{R}^5\text{R}^6$, $-\text{SO}_3\text{M}^{1/1/L}$, $-\text{SO}_2\text{NM}^{6/1/L}\text{R}^2$, $-\text{PO}_3(\text{NR}^7\text{R}^8\text{R}^9\text{R}^{10})_2$ and/or $-\text{PO}_3\text{M}^{2/2/L}$.

The symbols R^3 , R^4 , R^5 , R^6 , R^7 , R^8 , R^9 and R^{10} are the
 20 same or different and each represents H or an alkyl group containing 1 to 4 carbon atoms. The symbol R^2 represents H, $\text{M}^{7/1/L}$, an alkyl group or a sulfonyl-containing group. The symbols M^1 , M^2 , M^6 and M^7 are the same or different and each represents a metal having a valence of L. The metal having
 25 a valence of L is a metal belonging to the group 1, 2, 4, 8, 11, 12 or 13 of the long-form periodic table.

The above-mentioned acid/acid salt groups are preferably sulfonic acid groups, $-\text{SO}_3\text{NR}^3\text{R}^4\text{R}^5\text{R}^6$ and/or $-\text{SO}_3\text{M}^{1/1/L}$ (in which R^3 , R^4 , R^5 , R^6 and M^1 are as defined above).

30 The above-mentioned fluoropolymer preferably contains the acid/acid salt groups mentioned above in an amount of not smaller than 0.1 milliequivalent/g but not greater than 2.5 milliequivalents/g, more preferably not smaller than 0.5 milliequivalent/g but not greater than 2
 35 milliequivalents/g, although that amount is not

particularly restricted.

The above-mentioned fluoropolymer is preferably one obtained by subjecting a fluoropolymer precursor to heat treatment. The fluoropolymer precursor contains the above-mentioned acid/acid salt groups and has $-\text{CF}_2\text{COOX}$ groups (in which X represents H, $\text{NR}^{11}\text{R}^{12}\text{R}^{13}\text{R}^{14}$ or $\text{M}^4_{1/L}$; R^{11} , R^{12} , R^{13} and R^{14} are the same or different and each represents H or an alkyl group containing 1 to 4 carbon atoms and M^4 represents a metal having a valence of L, the metal having a valence of L being as mentioned above) at polymer chain terminals. The heat treatment is not particularly restricted but may be one effective in converting the above-mentioned $-\text{CF}_2\text{COOX}$ (X being as defined above) to $-\text{CF}_2\text{H}$, for example the method to be described later herein.

The above-mentioned fluoropolymer precursor preferably has a content (mmol) of $-\text{CF}_2\text{COOX}$ groups at polymer chain terminals, of 0.3 to 22 mmol/kg per kilogram of the polymer. A more preferred lower limit to the content of $-\text{CF}_2\text{COOX}$ groups at polymer chain terminals is 0.5, a still more preferred lower limit thereto is 1, and a more preferred upper limit thereto is 18.

The fluoropolymer of the invention generally has $-\text{CF}_2\text{H}$ groups resulting from conversion of the $-\text{CF}_2\text{COOX}$ groups upon the above-mentioned heat treatment. The percentage of the above-mentioned conversion is the value calculated according to the equation:

$$\text{Conversion rate (\%)} = \{1 - (I/I_0)\} \times 100$$

where I_0 is the $-\text{CF}_2\text{COOX}$ peak intensity before heat treatment and I is the $-\text{CF}_2\text{COOX}$ peak intensity after heat treatment, with an IR spectrum of a polymer having no $-\text{CF}_2\text{COOX}$ terminal as prepared separately being used as a zero standard for peak intensity comparison between the spectra before and after heat treatment according to the method of producing a fluoropolymer of the invention. The conversion rate is preferably not lower than 60%, more

preferably not lower than 80%, still more preferably not lower than 90%.

When the conversion rate is 60% or above, fluoropolymers having a content (mmol) of $-CF_2H$ groups of 0.18 to 13.2 mmol/kg per kilogram of the polymer are obtained. When the above-mentioned conversion rate is 60% or above with respect to the fluoropolymer precursor before heat treatment, a preferred lower limit to the content of $-CF_2H$ groups at polymer chain terminals is 0.5, a more preferred lower limit is 1, and a preferred upper limit is 18 (mmol/kg).

In the practice of the invention, the fluoropolymer precursor is preferably one obtained by polymerizing a perhalovinyl ether derivative represented by the general formula (I):

wherein Y^1 represents F, Cl or a perfluoroalkyl group, n represents an integer of 0 to 3, the n atoms/groups of Y^1 may be the same or different, Y^2 represents F or Cl, m represents an integer of 1 to 5, the m atoms of Y^2 may be the same or different and Z represents F, Cl, Br, I, $-OM^{5}_{1/L}$ or $-ONR^{15}R^{16}R^{17}R^{18}$; M^5 represents a metal having a valence of L and the metal having a valence of L is as defined above, and R^{15} , R^{16} , R^{17} and R^{18} are the same or different and each represents H or an alkyl group containing 1 to 4 carbon atoms.

The fluoropolymer precursor may be an acid salt type group-containing polymer resulting from conversion, by hydrolysis treatment, of a polymer containing groups other than the above-mentioned acid/acid salt group but convertible to the acid/acid salt groups, for example in the case where Z in $-SO_2Z$ in the above general formula (I) is F, Cl, Br or I or in the case where the polymer contains $-SO_2NR^{22}R^{23}$ groups (in which R^{22} and R^{23} are the same or different and each represents an alkyl group or a sulfonyl-

containing group). The above-mentioned fluoropolymer precursor may also be a polymer obtained by subjecting a polymer containing groups (hereinafter, "first groups") falling under the above-defined class of acid/acid salt groups to hydrolysis treatment and/or acid treatment to convert the first groups to groups (hereinafter, "second groups") also falling under the class of acid/acid salt groups but differing from the above-mentioned first groups. The conversion of the first groups to the second groups includes, among others, the conversion of the species of the acid salt group-constituting metal having a valence of L to another species, the conversion of acid groups to acid salt groups, and the conversion of acid salt groups to acid groups.

When the group $\text{-SO}_2\text{Z}$ in the above general formula (I) is not the above-mentioned acid/acid salt group, the fluoropolymer precursor mentioned above is one resulting from some acid/acid salt group conversion treatment, after the above-mentioned polymerization, for the conversion of the above-mentioned $\text{-SO}_2\text{Z}$ to the above-mentioned acid/acid salt group.

By saying "the group $\text{-SO}_2\text{Z}$ in the general formula (I) is not the above-mentioned acid/acid salt group" herein, it is meant that the group $\text{-SO}_2\text{Z}$ in the above general formula (I) is different in kind from the acid/acid salt group which the fluoropolymer of the invention as obtained by subjecting the fluoropolymer precursor having that $\text{-SO}_2\text{Z}$ group to heat treatment has. In case the $\text{-SO}_2\text{Z}$ group in the above general formula (I) is not the acid/acid salt group intended to be owned by the fluoropolymer, it becomes necessary to convert this $\text{-SO}_2\text{Z}$ to the desired acid/acid salt group after polymerization of the perhalovinyl ether derivative mentioned above prior to the heat treatment mentioned above, since that heat treatment will not transform the acid/acid salt group.

The acid/acid salt group conversion treatment mentioned above is not particularly restricted but may be any treatment provided that it can convert the $-\text{SO}_2\text{Z}$ in the above general formula (I) to the desired acid/acid salt group mentioned above. As for the acid/acid salt group conversion treatment, when Z in $-\text{SO}_2\text{Z}$ in the above general formula (I) is F, Cl, Br or I, there may be mentioned, for example, the hydrolysis treatment for converting the above-mentioned $-\text{SO}_2\text{Z}$ to an acid/acid salt group. When Z in $-\text{SO}_2\text{Z}$ in the above general formula (I) is $-\text{OM}^5_{1/L}$ or $-\text{ONR}^{15}\text{R}^{16}\text{R}^{17}\text{R}^{18}$ (in which M^5 , R^{15} , R^{16} , R^{17} and R^{18} are as defined above; in this paragraph, the same also shall apply), the above-mentioned acid/acid salt group conversion treatment may also be a treatment for converting the above-mentioned $\text{M}^5_{1/L}$ or $-\text{NR}^{15}\text{R}^{16}\text{R}^{17}\text{R}^{18}$ to another species in the category of $\text{M}^5_{1/L}$ or $-\text{NR}^{15}\text{R}^{16}\text{R}^{17}\text{R}^{18}$ or, when Z in $-\text{SO}_2\text{Z}$ in the above general formula (I) is $-\text{OM}^5_{1/L}$ or $-\text{ONR}^{15}\text{R}^{16}\text{R}^{17}\text{R}^{18}$, it may be an acid treatment for converting the above-mentioned $-\text{SO}_2\text{Z}$ to $-\text{SO}_3\text{H}$.

Further, $-\text{SO}_2\text{Z}$ in the above general formula (I) can be converted to $-\text{SO}_2\text{NR}^1\text{R}^2$ (in which R^1 and R^2 are as defined above) by reacting with NHR^1R^2 , for instance.

The method of producing a fluoropolymer of the invention is a method of producing a fluoropolymer by subjecting a fluoropolymer precursor containing acid/acid salt groups and having $-\text{CF}_2\text{COOX}$ (in which X represents H, $\text{NR}^{11}\text{R}^{12}\text{R}^{13}\text{R}^{14}$ or $\text{M}^4_{1/L}$; R^{11} , R^{12} , R^{13} and R^{14} are the same or different and each represents H or an alkyl group containing 1 to 4 carbon atoms and M^4 represents a metal having a valence of L, the metal having a valence of L being as defined above) groups at polymer chain terminals to heat treatment for the conversion of the $-\text{CF}_2\text{COOX}$ (X being as defined above) groups to $-\text{CF}_2\text{H}$ groups (hereinafter such conversion is sometimes referred to as "terminal group conversion").

The above-mentioned group $-\text{CF}_2\text{H}$ is a very stable

group as compared with $-\text{CF}_2\text{COOX}$ groups (X being as defined above) and, in ordinary fields of application of the fluoropolymer obtained, for example in the fields of use in which the fluoropolymer is heated at high temperatures, it
5 remains still stable.

The method of producing a fluoropolymer of the invention consists in stabilizing polymer chain terminals by heat treatment and, therefore, is superior to the conventional fluorination treatment of polymer chain
10 terminals in that the fluorination equipment required in the art is no more necessary and in that those side reactions possibly occurring in fluorination treatment are no more encountered. The "fluorination treatment" so referred to herein is a treatment carried out under feeding
15 of a fluorine source from outside the system for fluorinating thermally unstable groups such as $-\text{COOX}$.

In the method of producing a fluoropolymer of the invention, the fluoropolymer precursor is one obtained by polymerizing a perhalovinyl ether derivative of the general
20 formula (I) given above. In the general formula (I), Y^2 is preferably F, n is preferably 0 or 1, and m is preferably 2 or 3 and, more preferably, n is 0 and m is 2.

The fluoropolymer precursor is preferably an at least binary copolymer obtained by polymerizing the above-
25 mentioned perhalovinyl ether derivative and a monomer copolymerizable with the perhalovinyl ether derivative.

The monomer copolymerizable with the perhalovinyl ether derivative is, for example, an ethylenic fluoromonomer. The ethylenic fluoropolymer is not
30 particularly restricted but may be any one having a vinyl group and containing fluorine atoms in lieu of all carbon-bound hydrogen atoms. It is different from the above-mentioned perhalovinyl ether derivative, however.

The ethylenic fluoromonomer includes, among others,
35 haloethylenic monomers represented by the general formula:

wherein R_f^2 represents a fluorine or chlorine atom, $-\text{R}_f^3$ or $-\text{OR}_f^3$ in which R_f^3 represents a straight or branched fluoroalkyl group containing 1 to 9 carbon atoms and optionally containing an ether oxygen atom or atoms, and hydrogen-containing fluoroethylenic monomers represented by the general formula:

wherein Y^3 represents H or a fluorine atom and Y^4

represents H, a fluorine or chlorine atom, $-\text{R}_f^4$ or $-\text{OR}_f^4$; R_f^4 represents a straight or branched fluoroalkyl group containing 1 to 9 carbon atoms and optionally containing an ether oxygen atom or atoms.

Preferred as the ethylenic fluoromonomer are $\text{CF}_2=\text{CF}_2$, $\text{CH}_2=\text{CF}_2$, $\text{CF}_2=\text{CFCl}$, $\text{CF}_2=\text{CFH}$, $\text{CH}_2=\text{CFH}$, $\text{CF}_2=\text{CFCF}_3$ and/or fluorovinyl ethers represented by $\text{CF}_2=\text{CF}-\text{O}-\text{R}_f^5$; R_f^5 represents a fluoroalkyl group containing 1 to 9 carbon atoms or a fluoropolyether group containing 1 to 9 carbon atoms. The fluorovinyl ethers are preferably those in which R_f^5 is a perfluoroalkyl group containing 1 to 3 carbon atoms.

The ethylenic fluoromonomer is preferably a perhaloethylenic monomer, in particular a perfluoroethylenic monomer, and more preferably is $\text{CF}_2=\text{CF}_2$. Either one single species or a combination of two or more species of the ethylenic fluoromonomer can be used.

The fluoropolymer precursor may also be one obtained by further subjecting another copolymerizable monomer, in addition to the ethylenic fluoromonomer mentioned above, to polymerization to provide the fluoropolymer with various functions at usage levels at which the fundamental performance characteristics of the fluoropolymer will not be adversely affected. The other copolymerizable monomer is not particularly restricted but may be appropriately selected from among copolymerizable monomers according to

the intended purpose of introduction, for example, polymerization rate control, polymer composition control, elasticity modulus and other mechanical physical properties control and/or crosslinking site introduction. Mention may
5 be made of a monomer having two or more unsaturated bonds, for example a perfluorodivinyl ether, and a cyano group-containing monomer, among others.

The above-mentioned fluoropolymer precursor preferably has a perhalovinyl ether derivative unit content
10 of 5 to 40 mole percent. At levels lower than 5 mole percent, the fluoropolymer obtained may show decreased performance characteristics as an electrolyte in some instances and, at levels exceeding 40 mole percent, the membrane-shaped moldings made of the fluoropolymer obtained
15 may become unsatisfactory in mechanical strength in certain cases. A more preferred lower limit is 8 mole percent, and a more preferred upper limit is 35 mole percent. In cases where the fluoropolymer of the invention has a higher sulfonic acid group concentration on the fluoropolymer
20 particle surface than in the fluoropolymer particle inside, the perhalovinyl ether derivative unit content on the fluoropolymer particle surface is required to be within the range mentioned above.

The term "perhalovinyl ether derivative unit" as used
25 herein means a segment derived from the perhalovinyl ether derivative and constituting a part of the molecular structure of the fluoropolymer precursor. The "perhalovinyl ether derivative unit content" so referred to herein is the proportion of the number of moles of the
30 perhalovinyl ether derivative from which the perhalovinyl ether derivative units are derived to the number of moles of the monomers from which all the monomer units in the fluoropolymer precursor molecule are derived. The "all monomer units" include all segments derived from the
35 monomers constituting the molecular structure of the

fluoropolymer precursor. The "monomers from which all the monomer units are derived" therefore correspond to the total amount of the monomers that have participated in constituting the fluoropolymer precursor. The perhalovinyl ether derivative unit content is the value obtained by infrared absorption spectrometry [IR] or by molten-state NMR spectrometry at 300°C.

In producing the fluoropolymer precursor by polymerization, such conventional methods of polymerization, for example, emulsion polymerization, suspension polymerization, bulk polymerization and solution polymerization, can be employed. Among them, emulsion polymerization and solution polymerization are preferably used. When the fluoropolymer precursor is one obtained by emulsion polymerization or solution polymerization, it generally has $-\text{CF}_2\text{COOX}$ groups (X being as defined above) at polymer chain terminals and, therefore, the method of producing a fluoropolymer of the invention can be advantageous applied thereto.

The fluoropolymer precursor mentioned above may constitute a powder, dispersion, solution or membrane-shaped moldings.

In accordance with the method of producing a fluoropolymer of the invention, the fluoropolymer precursor preferably constituting such a powder, dispersion, solution or membrane-shaped moldings as mentioned above is subjected to heat treatment to convert the above-mentioned $-\text{CF}_2\text{COOX}$ (X being as defined above) groups to $-\text{CF}_2\text{H}$ groups. Generally, this heat treatment neither transforms the above-mentioned acid/acid salt groups nor causes any change in the morphology of the powder, dispersion, solution or membrane-shaped moldings.

The fluoropolymer precursor powder may be a powder of the polymer obtained by polymerizing the above-mentioned perhalovinyl ether derivative and, when this polymer is a

polymer having groups other than the above-mentioned acid/acid salt groups but convertible to the acid/acid salt groups, for example when Z in $-\text{SO}_2\text{Z}$ is F, Cl, Br or I, it is converted to a fluoropolymer precursor by subjecting the same to the hydrolysis treatment to be described later herein for the conversion to the above-mentioned acid/acid salt groups such as $-\text{SO}_3\text{M}^1_{1/\text{L}}$ or $-\text{SO}_3\text{NR}^3\text{R}^4\text{R}^5\text{R}^6$ (M^1 , L, R^3 , R^4 , R^5 and R^6 being as defined above). When the polymerization of the perhalovinyl ether derivative is carried out in the manner of emulsion polymerization, the above-mentioned powder is, for example, one obtained from the liquid just after polymerization by an appropriate coagulation procedure and purification procedure and, in the case of solution polymerization, it is, for example, one obtained by removing the reaction solvent used by a conventional method, followed by an appropriate purification procedure.

The fluoropolymer precursor dispersion may be an emulsion polymerization liquid containing the polymer obtained by polymerizing the perhalovinyl ether derivative, or it may be one obtained by dispersing the powder mentioned above in an appropriate dispersion medium. When the polymer is a polymer having groups other than the above-mentioned acid/acid salt groups but convertible to the acid/acid salt groups, for example when Z in $-\text{SO}_2\text{Z}$ is F, Cl, Br or I, it is converted to a fluoropolymer precursor by subjecting the same to the hydrolysis treatment to be described later herein for the conversion to the above-mentioned acid/acid salt groups such as $-\text{SO}_3\text{M}^1_{1/\text{L}}$ or $-\text{SO}_3\text{NR}^3\text{R}^4\text{R}^5\text{R}^6$ (M^1 , L, R^3 , R^4 , R^5 and R^6 being as defined above).

The fluoropolymer precursor solution is one obtained by dissolving the powder mentioned above in an appropriate liquid medium by the method disclosed in Japanese Kohyo Publication 2001-504872 or U.S. Patent No. 4,433,082, for instance. The liquid medium is, for example, a water/isopropyl alcohol mixed solvent, and the solution

mentioned above can be obtained by heating in this mixed solvent at 230 to 250°C.

The reduced viscosity of the above-mentioned solution increases as the concentration decreases, whereas the
5 dispersion shows no such changes in reduced viscosity and, in this respect, can be distinguished from the solution.

The above-mentioned solution contains rod-form minute resin particles of the fluoropolymer precursor with an aspect ratio of about 5, whereas the fluoropolymer
10 precursor particles contained in the dispersion comprise spherical particles with an average particle diameter of about 10 nm. In this respect, too, they are distinguishable from each other.

The membrane-shaped moldings made of the
15 fluoropolymer precursor mentioned above may be ones obtained by membrane formation under melting using the above-mentioned powder or by pressure molding using the method described in Japanese Kokai Publication S58-37031, for instance, or membrane-shaped ones produced by membrane
20 casting using the above-mentioned dispersion or solution. When the membrane-shaped moldings are ones produced by membrane formation under melting using a powder of a polymer having groups other than the above-mentioned acid/acid salt groups but convertible to the acid/acid salt
25 groups, for example when Z in $-\text{SO}_2\text{Z}$ is F, Cl, Br or I, the polymer is converted to a fluoropolymer precursor by subjecting the moldings to the hydrolysis treatment to be described later herein, if desired followed by acid
treatment, for the conversion to the above-mentioned
30 acid/acid salt groups such as $-\text{SO}_3\text{M}^1_{1/\text{L}}$ or $-\text{SO}_3\text{NR}^3\text{R}^4\text{R}^5\text{R}^6$ (M^1 , L, R^3 , R^4 , R^5 and R^6 being as defined above).

The fluoropolymer precursor mentioned above may also be one obtained by hydrolysis treatment/acid treatment further followed by treatment for removing low-molecular-
35 weight substances (hereinafter sometimes referred to as

"low-molecular-weight substance removing treatment"). The low-molecular-weight substances are, for example, monomers remaining after the emulsion polymerization mentioned above, polymerization initiator residues, unnecessary low-molecular-weight polymers, products formed upon hydrolysis treatment of the fluoropolymer precursor, and so forth. When residues of the emulsifier used in emulsion polymerization are present, these can also be removed.

The low-molecular-weight substance removing treatment is not particularly restricted but may be, for example, a centrifugation method, electrophoretic method or ultrafiltration method. The ultrafiltration method is preferably used, however.

The ultrafiltration method is not particularly restricted but may be any method using an ultrafiltration apparatus having an ultrafiltration membrane for the removal of low-molecular-weight substances. Thus, for example, mention may be made of the centrifugal ultrafiltration method and circulating ultrafiltration method. Suitably usable as the ultrafiltration membrane-equipped ultrafiltration apparatus are commercially available ones, for example such ones for laboratory use as Centriprep (trademark, product of Amicon), Millitan (trademark, product of Millipore) and Pericon (trademark, product of Millipore). The ultrafiltration process mentioned above can also serve to concentrate the fluoropolymer precursor obtained.

The low-molecular-weight substance removing treatment may be carried out after the above-mentioned hydrolysis treatment or, when an acid treatment is further carried out after the hydrolysis treatment, the treatment in question may be carried out before the acid treatment.

The conversion of $-\text{CF}_2\text{COOX}$ (X being as defined above) to $-\text{CF}_2\text{H}$ by the above-mentioned heat treatment presumably proceeds according to the following reaction formula:

In the above reaction formula, the source of supply of the proton $[\text{H}^+]$ for the addition to $-\text{CF}_2^-$ is not particularly restricted but generally is H_2O occurring in the environment surrounding the fluoropolymer precursor. Therefore, the heat treatment mentioned above is generally carried out in the presence of H_2O . The " H_2O ", so referred to herein, which is generally caused to be present in carrying out the heat treatment, means H_2O on the molecule level. The " H_2O " of course constitutes "water" which is macroscopic in the sense that it can be recognized by the eye. However, it is not always necessary to be such macroscopic "water" if it is present at least on the molecule level. In the present specification, the above-mentioned macroscopic "water" is sometimes referred to merely as "water" or as "moisture".

When the above-mentioned fluoropolymer precursor constitutes an aqueous dispersion liquid as the dispersion, the H_2O generally caused to be present in the above-mentioned heat treatment can be supplied from the aqueous medium in this aqueous dispersion liquid. When the fluoropolymer precursor constitutes a powder or a membrane, the H_2O can be supplied by the moisture absorbed by the acid/acid salt groups which the fluoropolymer precursor has and, therefore, it is not necessary to add water from outside the system.

When the fluoropolymer precursor constitutes a dispersion or solution, it is necessary to carry out the acid/acid salt groups heating at a temperature not lower than the boiling point of water; therefore, it is generally preferable that the heat treatment be carried out in a closed autoclave under pressurization.

The time required for the above heat treatment can be properly selected according to the kind of the acid/acid salt groups which the fluoropolymer precursor has, whether

the fluoropolymer precursor occurs as a powder, dispersion, solution or membrane-shaped molding, the affinity of the fluoropolymer precursor for the solvent, and the heat treatment temperature, among others.

5 The fluoropolymer precursor is preferably constitutes membrane-shaped moldings. When the fluoropolymer precursor constitutes membrane-shaped moldings, the membrane-shaped moldings after the above-mentioned heat treatment can be directly used when they are to be used in the form of
10 membranes.

 The above-mentioned heat treatment can convert - CF_2COOX (X being as defined above) to $-\text{CF}_2\text{H}$ and, in carrying out the method of producing a fluoropolymer of the invention, the fluoropolymer precursor is preferably heated
15 at 120 to 400°C. At lower than 120°C, the decarboxylation reaction can hardly proceed in some cases and, at above 400°C, the polymer main chain itself may be decomposed in certain instances. A preferred upper limit to the heat treatment temperature is 350°C, and a more preferred upper
20 limit thereto is 300°C.

 The above heat treatment can also be carried out by heating the fluoropolymer precursor in the presence of water or an organic solvent having affinity for water at 120 to 250°C, more preferably by heating at 120 to 220°C,
25 still more preferably at 120 to 200°C. The "water", so referred to herein, which is caused to be present in the above-mentioned heat treatment, is not H_2O on the molecule level but macroscopic water, including, for example, moisture absorbed by the acid/acid salt groups, as
30 mentioned hereinabove.

 The decarboxylation temperature can be lowered in the presence of an organic solvent having affinity for water. In particular, when the fluoropolymer precursor constitutes membrane-shaped moldings, the moldings may be deformed at
35 elevated temperatures and, therefore, a high-boiling

organic solvent such as a phosphate ester is preferably caused to coexist to thereby lower the treatment temperature and maintain the dimensional stability.

The decarboxylation reaction proceeds at a
5 sufficiently high rate in the presence of an organic solvent having affinity for water. Therefore, even if the heat treatment is carried out at a temperature equal to or higher than the boiling point of the organic solvent, the terminal group conversion can be finished before exhaustion
10 of the organic solvent by evaporation.

As far as the conventional method of stabilizing polymer chain terminal carboxyl groups by heating a fluoropolymer having side chain terminal $-\text{SO}_2\text{F}$ groups at 200°C or above is concerned, it is not known in the art
15 that the addition of water becomes unnecessary owing to the presence of the above-mentioned acid/acid salt groups.

The above-mentioned organic solvent having affinity for water is preferably a polar solvent, more preferably a polar solvent having a boiling point exceeding 100°C but
20 not exceeding 300°C. The organic solvent having affinity for water is not particularly restricted but may be any of those having polarity and having a boiling point exceeding 100°C but not exceeding 300°C, such as phosphate esters, cyclic amides or cyclic amide derivatives, imidazolidine or
25 imidazolidine derivatives, ethylene oxide oligomer monohydroxy ethers, hexamethylphosphoric triamide, dimethyl sulfoxide and tetramethylurea. One or a combination of two or more of these can be used.

The phosphate esters are not particularly restricted
30 but include, among others, phosphoric acid triesters derived from phosphoric acid and alcohols containing 1 to 5 carbon atoms. As the phosphoric acid triesters, there may be mentioned trimethyl phosphate, triethyl phosphate, etc.

The cyclic amides or cyclic amide derivatives are not
35 particularly restricted but include, among others,

pyrrolidone at least one hydrogen atom of which may optionally be substituted by an alkyl group containing 1 to 5 carbon atoms. As such pyrrolidone, there may be mentioned 2-methylpyrrolidone, among others.

5 The above-mentioned imidazolidine or imidazolidine derivatives are not particularly restricted but mention may made of imidazolidine at least one hydrogen atom of which may optionally be substituted by an alkyl group containing 1 to 5 carbon atoms. As such imidazolidine, there may be
10 mentioned 3,4-dimethylimidazolidine and the like.

 The above-mentioned ethylene oxide oligomer monohydroxy ethers are not particularly restricted but molecules resulting from ether bonding between a 2 to 10 mole adduct of ethylene oxide and one alkyl group
15 containing 1 to 10 carbon atoms are preferred. The above-mentioned number of moles of addition of ethylene oxide is an average value for an aggregate of such ethylene oxide oligomer monohydroxy ether molecules as mentioned above. As the ethylene oxide oligomer monohydroxy ethers, there
20 may be mentioned, for example, diethylene glycol monoalkyl ethers and triethylene glycol monoalkyl ethers and, as specific examples of such, there may be mentioned diethylene glycol momomethyl ether and triethylene glycol monomethyl ether.

25 The membrane-shaped moldings, preferably electrolyte membranes, made of the above-mentioned fluoropolymer of the invention also constitute another aspect of the present invention.

 The electrolyte membranes may have a membrane
30 thickness of 1 to 200 μm , for instance.

 The immobilized active substance material of the invention comprises the above-mentioned fluoropolymer and an active substance.

 The active substance is not particularly restricted
35 but may be any one capable of showing activity in the

immobilized active substance material. It can be properly selected according to the intended use of the immobilized active substance material of the invention; for example, a catalyst can be used in certain cases.

5 The catalyst is not particularly restricted but any of those generally used as electrode catalysts, including, among others, metals containing platinum, ruthenium and/or the like; and those organic metal complexes generally containing at least one metal species as the central metal
10 in which at least one central metal is platinum or ruthenium. Although the metals containing platinum, ruthenium and/or the like may be ruthenium-containing metals, for example ruthenium as a simple substance, platinum-containing metals are preferred. The platinum-
15 containing metals are not particularly restricted but mention may be made of, for example, platinum as a simple substance (platinum black); and platinum-ruthenium alloys. The catalyst mentioned above is generally used in a form carried on a support such as silica, alumina or carbon.

20 The membrane-electrode assembly [MEA] of the invention comprises the immobilized active substance material mentioned above. The membrane-electrode assembly may contain another substance other than the immobilized active substance material mentioned above provided that
25 said substance will not affect the properties of the immobilized active substance material.

 The solid polymer electrolyte fuel cell of the invention comprises the membrane-electrode assembly mentioned above. The solid polymer electrolyte fuel cell
30 is not particularly restricted provided that it comprises the membrane-electrode assembly mentioned above.

 The solid polymer electrolyte fuel cell of the invention comprises the above-mentioned electrolyte membrane. The solid polymer electrolyte fuel cell is not
35 particularly restricted provided that it comprises the

electrolyte membrane mentioned above. Generally, it may be one comprising such solid polymer electrolyte fuel cell constituent elements as electrodes.

Each of the above-mentioned immobilized active substance material, electrolyte membrane and solid polymer electrolyte fuel cell is one produced by using a fluoropolymer containing acid/acid salt groups and, preferably, it is one obtained by using a fluoropolymer containing acid groups.

EFFECTS OF THE INVENTION

The method of producing a fluoropolymer of the invention, which has the constitution described hereinabove, can give fluoropolymers excellent in stability and improved in durability in a simple and easy manner.

BEST MODES FOR CARRYING OUT THE INVENTION

The following examples illustrate the present invention more specifically. These examples are, however, by no means limitative of the scope of the present invention.

In the examples, various measurements were made using the following methods.

1. Functional group assaying by IR

Each polymer sample was heat-pressed at 270°C and 10 MPa for 20 minutes, and the thus-prepared membrane with a thickness of 150 to 200 μm was subjected to spectrometry using an FT-IR spectroscope.

2. Stability testing using Fenton's reagent

Each polymer sample was heat-pressed at 270°C and 10 MPa for 20 minutes and then polymer side chain terminal groups were converted to sulfonic acid groups. The thus-obtained membrane was used as a membrane for stability testing.

A 3 g-section of the membrane for stability testing

was immersed in a solution prepared by dissolving 1 mg of $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ in 20 ml of a 30% aqueous solution of hydrogen peroxide and placed in a bottle made of a tetrafluoroethylene/perfluoro(alkyl vinyl ether) copolymer, and the section was maintained there at 85°C for 20 hours. Then, after cooling to room temperature, the membrane for stability testing was taken out, and the fluoride ion concentration in the liquid phase was measured using a fluoride ion meter.

10 Example 1

(1) A 3000-ml stainless steel autoclave equipped with a stirrer was charged with 300 g of a 10% aqueous solution of $\text{C}_7\text{F}_{15}\text{COONH}_4$ and 1170 g of pure water, followed by sufficient evacuation and nitrogen substitution. After sufficient evacuation of the autoclave, tetrafluoroethylene [TFE] gas was introduced into the autoclave to a gage pressure of 0.2 MPa, and the temperature was raised to 50°C. Thereafter, 100 g of $\text{CF}_2=\text{CFOCF}_2\text{CF}_2\text{SO}_2\text{F}$ was injected into the autoclave, and the pressure was raised to a gage pressure of 0.7 MPa by introducing TFE gas. Then, an aqueous solution prepared by dissolving 0.5 g of ammonium persulfate [APS] in 60 g of pure water was injected into the autoclave to initiate the polymerization.

For supplementing that portion of TFE which had been consumed in polymerization, TFE was fed continuously so as to maintain the autoclave pressure at 0.7 MPa. The polymerization was continued while further feeding $\text{CF}_2=\text{CFOCF}_2\text{CF}_2\text{SO}_2\text{F}$ continuously in an amount corresponding to a mass ratio of 0.53 relative to the TFE fed.

At the time of arrival of the amount of TFE fed at 522 g, the autoclave inside pressure was released and the polymerization was thus discontinued. Then, after cooling to room temperature, 2450 g of a slightly turbid aqueous dispersion containing about 33% by mass of a fluoropolymer precursor was obtained.

A portion of the above-mentioned aqueous dispersion was taken and coagulated with nitric acid, and the coagulated matter was washed with water and dried and subjected to molten-state NMR spectrometry, which revealed
5 that the fluorovinyl ether derivative unit content in the fluoropolymer precursor was 19 mole percent.

(2) A 1200-g portion of the aqueous dispersion obtained was coagulated with nitric acid, and the coagulated matter was washed with water, dried at 90°C for 24 hours and
10 further dried at 120°C for 12 hours to give 400 g of a fluoropolymer powder.

The fluoropolymer powder obtained was immersed in a 20% (by mass) aqueous solution of potassium hydroxide and maintained in this state at 95°C for 24 hours for the
15 hydrolysis of $-\text{SO}_2\text{F}$ groups. This powder was collected by filtration, sufficiently washed with pure water and then dried at 90°C for 24 hours to give an $-\text{SO}_3\text{Na}$ group-containing powder. This powder was subjected to heat treatment in an electric oven at 300°C for 1 hour. Samples
20 of the powders before and after treatment were pelletized using KBr and subjected to IR spectroscopy. As a result, carboxyl group-due peaks were observed at about 1776 cm^{-1} and about 1807 cm^{-1} with the powder before treatment, while those peaks were not observed with the powder after heat
25 treatment.

[Preparation of a $-\text{CF}_2\text{H}$ -terminated type membrane]

Using a simplified membrane molding apparatus (product of Imoto Machinery), the fluoropolymer powder (not yet subjected to hydrolysis treatment after drying)
30 obtained from the aqueous dispersion was melt-molded at a temperature of 270°C into a 50- μm -thick membrane.

(3) The membrane obtained was immersed in a 20% (by mass) aqueous solution of potassium hydroxide and maintained in that state at 95°C for 24 hours for the hydrolysis of $-\text{SO}_2\text{F}$
35 groups. Then, the membrane was sufficiently washed with

pure water until the washings became neutral. An $\text{-SO}_3\text{Na}$ type membrane was thus obtained.

A part of this membrane was sufficiently dried, and four sheets prepared therefrom were piled up and subjected
5 to IR spectroscopy, upon which main chain terminal carboxyl group-due absorption peaks were observed at about 1776 cm^{-1} and about 1807 cm^{-1} .

[Polymer chain terminal group assaying]

(4) Then, this membrane was immersed in a 1:1 (by mass)
10 mixed solution composed of trimethyl phosphate and water for 5 minutes, then placed in a hot air circulation type drier at 190°C and heat-treated for 1 hour.

Four sheets prepared from the membrane obtained were piled up and subjected to IR spectroscopy. As a result, no
15 carboxyl group-due peaks were observed, and a $\text{-CF}_2\text{H}$ group-due peak was observed at about 3010 cm^{-1} .

[Stability testing using Fenton's reagent]

The membrane obtained as described above under (4) was subjected to stability testing using Fenton's reagent.
20 As a result, the fluoride ion concentration was found to be 6 ppm.

[Polymer chain terminal conversion rate determination]

The $\text{-SO}_3\text{Na}$ type membrane obtained as described above under (3) was placed, together with 5 g of water, in a 50-
25 cm^3 pressure vessel and, after tight sealing, subjected to heat treatment in an electric oven at 125°C for 1 hour. After sufficient cooling, a sample was taken out and dried at 110°C for 1 hour. Four sheets prepared therefrom were piled up and subjected to IR spectroscopy for carboxyl
30 group assaying in the same manner as described above under (4). Similarly, heat treatments were carried out varying the heating temperature to 150°C , 175°C , 200°C or 250°C , each time followed by carboxyl group assaying.

The carboxyl group content before heat treatment was
35 determined and found to be 10 mmol/kg.

The relation between heat treatment temperature and polymer chain terminal conversion rate is shown below in Table 1.

Heat treatment temperature °C	125	150	175	200	250
Polymer chain terminal conversion rate %	0	4	20	100	100

5 [Preparation of a $-\text{CF}_2\text{H}$ -terminated fluoropolymer dispersion]

(6) A 100-ml portion of the fluoropolymer precursor dispersion obtained as described above under (1) was 5-fold diluted with pure water and stirred in a 1000-ml beaker, and the $-\text{SO}_2\text{F}$ groups which the fluoropolymer precursor had were hydrolyzed at a temperature of 55°C while adding, by drops, a 10% (by mass) aqueous solution of sodium hydroxide to maintain the pH at 10 or above. About 3 hours later, no more pH drop was observed. However, the hydrolysis procedure was further continued for 2 hours and then terminated. During this process, no fluoropolymer precipitation was confirmed by the eye.

(7) The reaction mixture obtained as described above under (6) was subjected to centrifugal ultrafiltration using Centriprep YM-10 (product of Amicon) for removing low-molecular-weight substances and for fluoropolymer purification and concentration. The thus-obtained fluoropolymer dispersion contained 35% by mass of a fluoropolymer having stable $-\text{SO}_3\text{Na}$ groups.

(8) A 100-cc autoclave was charged with 30 g of the fluoropolymer dispersion obtained as described above under (7) and 15 g of trimethyl phosphate and, after tight sealing, the autoclave inside was maintained at 150°C for 2 hours to give a fluoropolymer dispersion composition for thin membrane molding.

(9) The fluoropolymer dispersion composition for thin membrane molding obtained as described above under (8) was placed in an evaporator and heated at 80°C for 3 hours

under evacuation. A white solid was obtained. This was cold pressed to give a thin membrane, which was subjected to IR spectroscopy. Any carboxyl group-due peaks were not observed.

5 Comparative Example 1

The membrane obtained as described above under (3) was subjected to stability testing using Fenton's reagent. The fluoride ion concentration was 22 ppm.

10

INDUSTRIAL APPLICABILITY

The fluoropolymer of the invention can be particularly suitably used in the field of solid polymer electrolyte fuel cells and in other fields where stability is required.

15
